What is Self-Assembly?

Self-assembly: no precise general definition

But roughly speaking:

- "process by which an organized structure can spontaneously form from simpler parts"
- "process in which components, either separate, or linked, spontaneously form ordered aggregates" *(G.M.Whitesides, PNAS, Vol.99, no.8, 2002)*

Most relevant research issues:

- Programming
- Complexity
- Fault-tolerance
- Self-healing
- Self-reproduction
- Evolution

Self-Assembly in Nature (Uncoded)

Other Examples

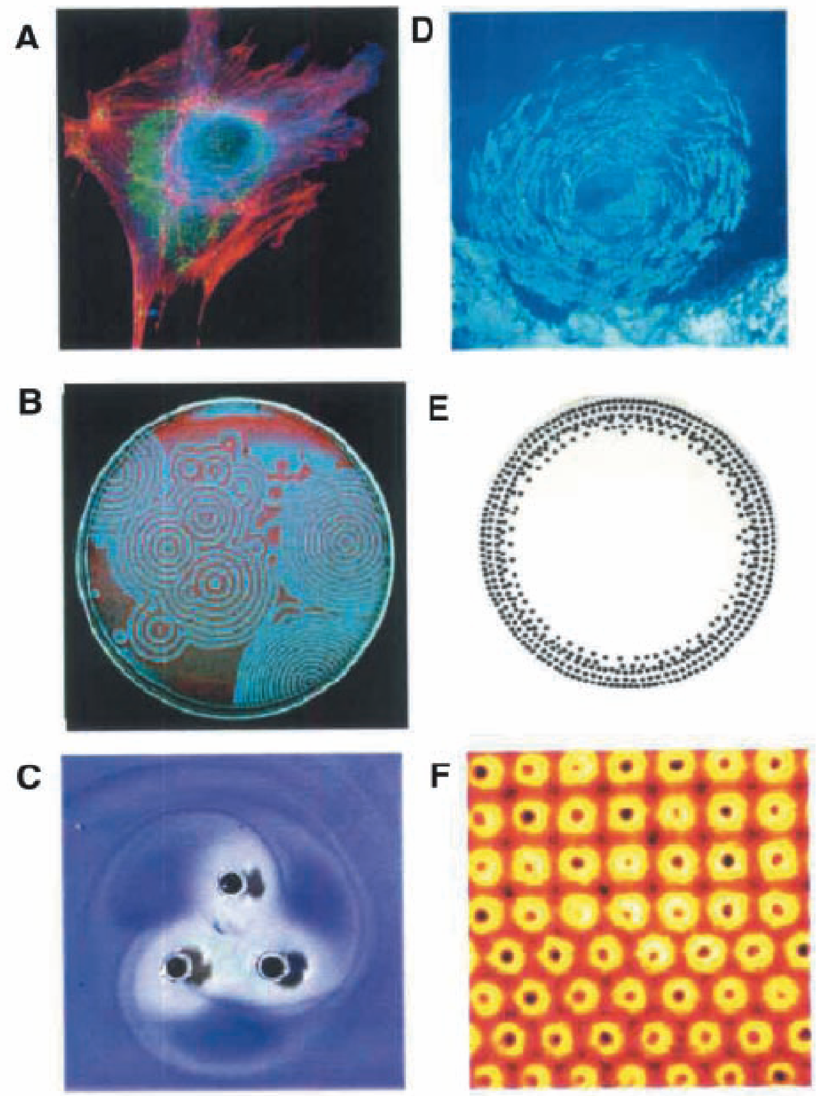

Fig. 2. Examples of dynamic self-assembly. **(A)** An optical micrograph of a cell with fluorescently labeled cytoskeleton and nucleus; microtubules (~24 nm in diameter) are colored red. **(B)** Reaction-diffusion waves in a Belousov-Zabatinski reaction in a 3.5-inch Petri dish. **(C)** A simple aggregate of three millimeter-sized, rotating, magnetized disks interacting with one another via vortex-vortex interactions. **(D)** A school of fish. **(E)** Concentric rings formed by charged metallic beads 1 mm in diameter rolling in circular paths on a dielectric support. **(F)** Convection cells formed above a micropatterned metallic support. The distance between the centers of the cells is ~2 mm. [Image credits: (A) from (*30*); (B) from (*26*); (C) from (*31*)]

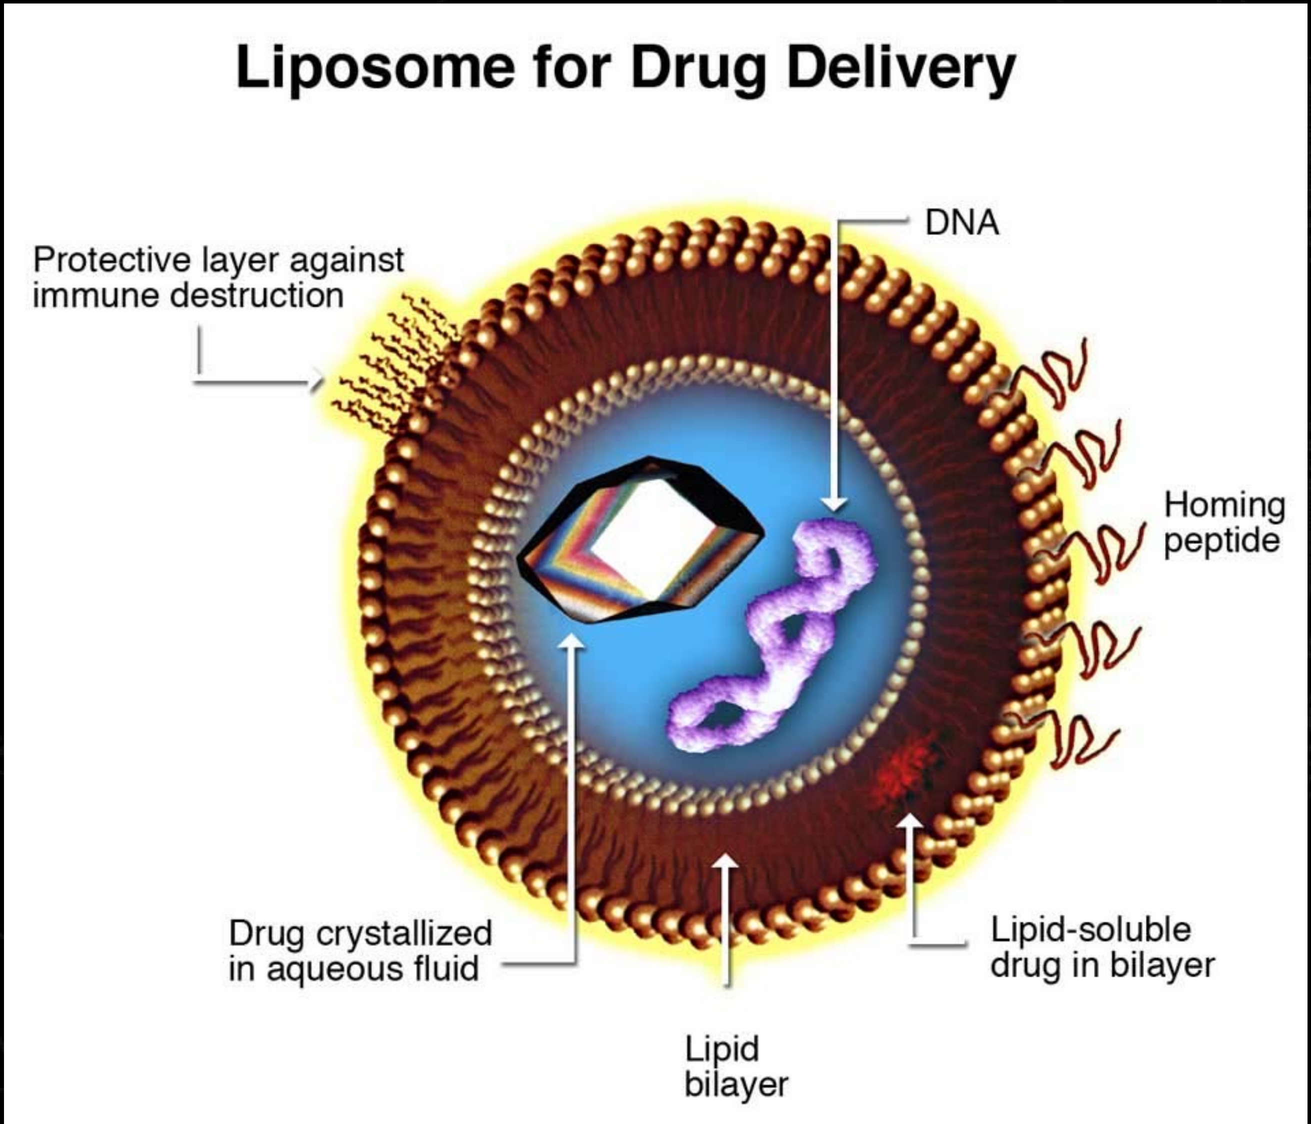
Whitesides and Grzybowski, 2002

Self-Assembly – Why Studying It?

- Self-assembly is about (spontaneous) transition of disorder to order
- Living cells self-assemble: understanding life will therefore require understanding self-assembly
- Self-assembly is one of the few practical strategies for making ensembles of nanostructures
- Manufacturing and robotics will benefit from self-assembly
- Self-assembly is common to many dynamic, multicomponent systems, from smart materials and self-healing structures to netted sensors and computer networks

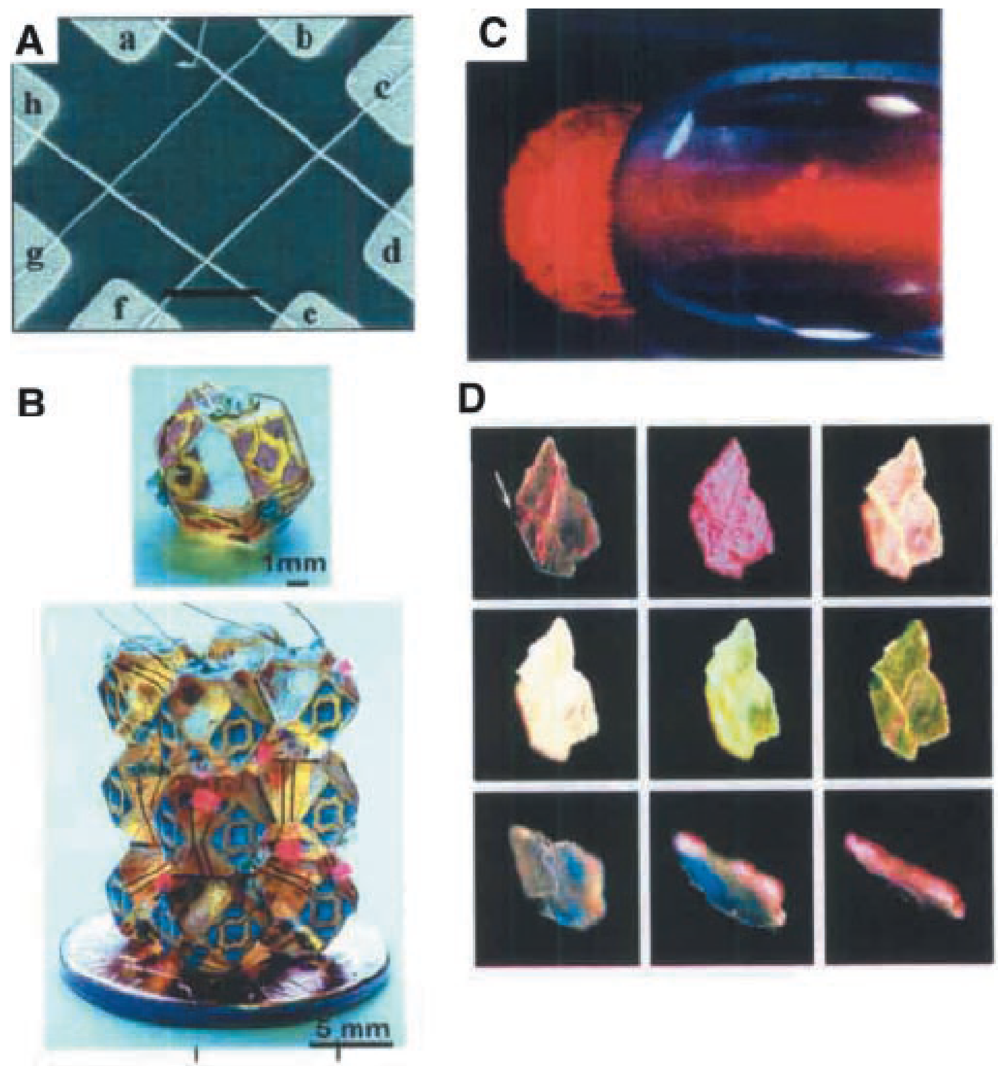
Whitesides and Grzybowski, 2002

Self-Assembly: Early Success



More Recent Successes

Fig. 3. Applications of self-assembly. **(A)** A 2 by 2 cross array made by sequential assembly of *n*-type InP nanowires with orthogonal flows. **(B)** Diffraction grating formed on the surface of a poly(dimethylsiloxane) sphere ~1 mm in diameter. The sphere was compressed between two glass slides, and its free surface was exposed to oxygen plasma. Upon release of compression, the oxidized surface of the polymer buckled with a uniform wavelength of ~20 μm. **(C)** Three-dimensional electronic circuits self-assembled from millimeter-sized polyhedra with electronic components (LEDs) embossed on their faces. **(D)** An artificial, ferromagnetic opal prepared by templated self-assembly of polymeric microbeads. The optical properties of the aggregate can be adjusted by modifying external magnetic field.



Whitesides and Grzybowski, 2002

Why Self-Assembly? Examples

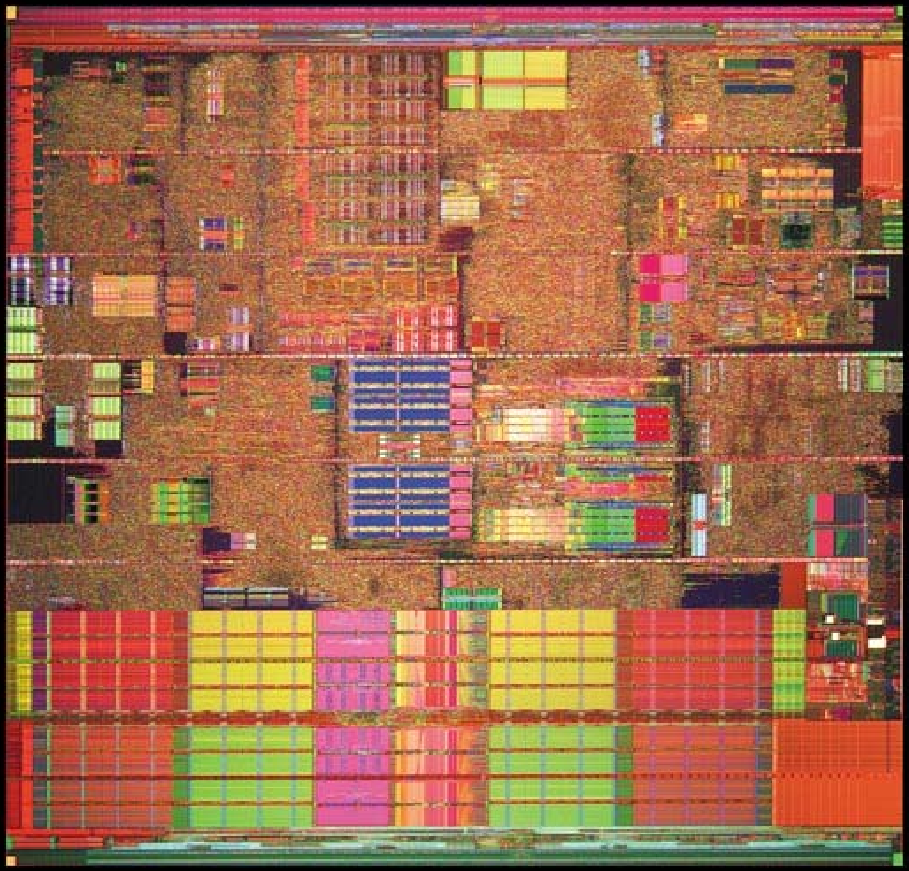
Movies:

Lego-car

Plane!

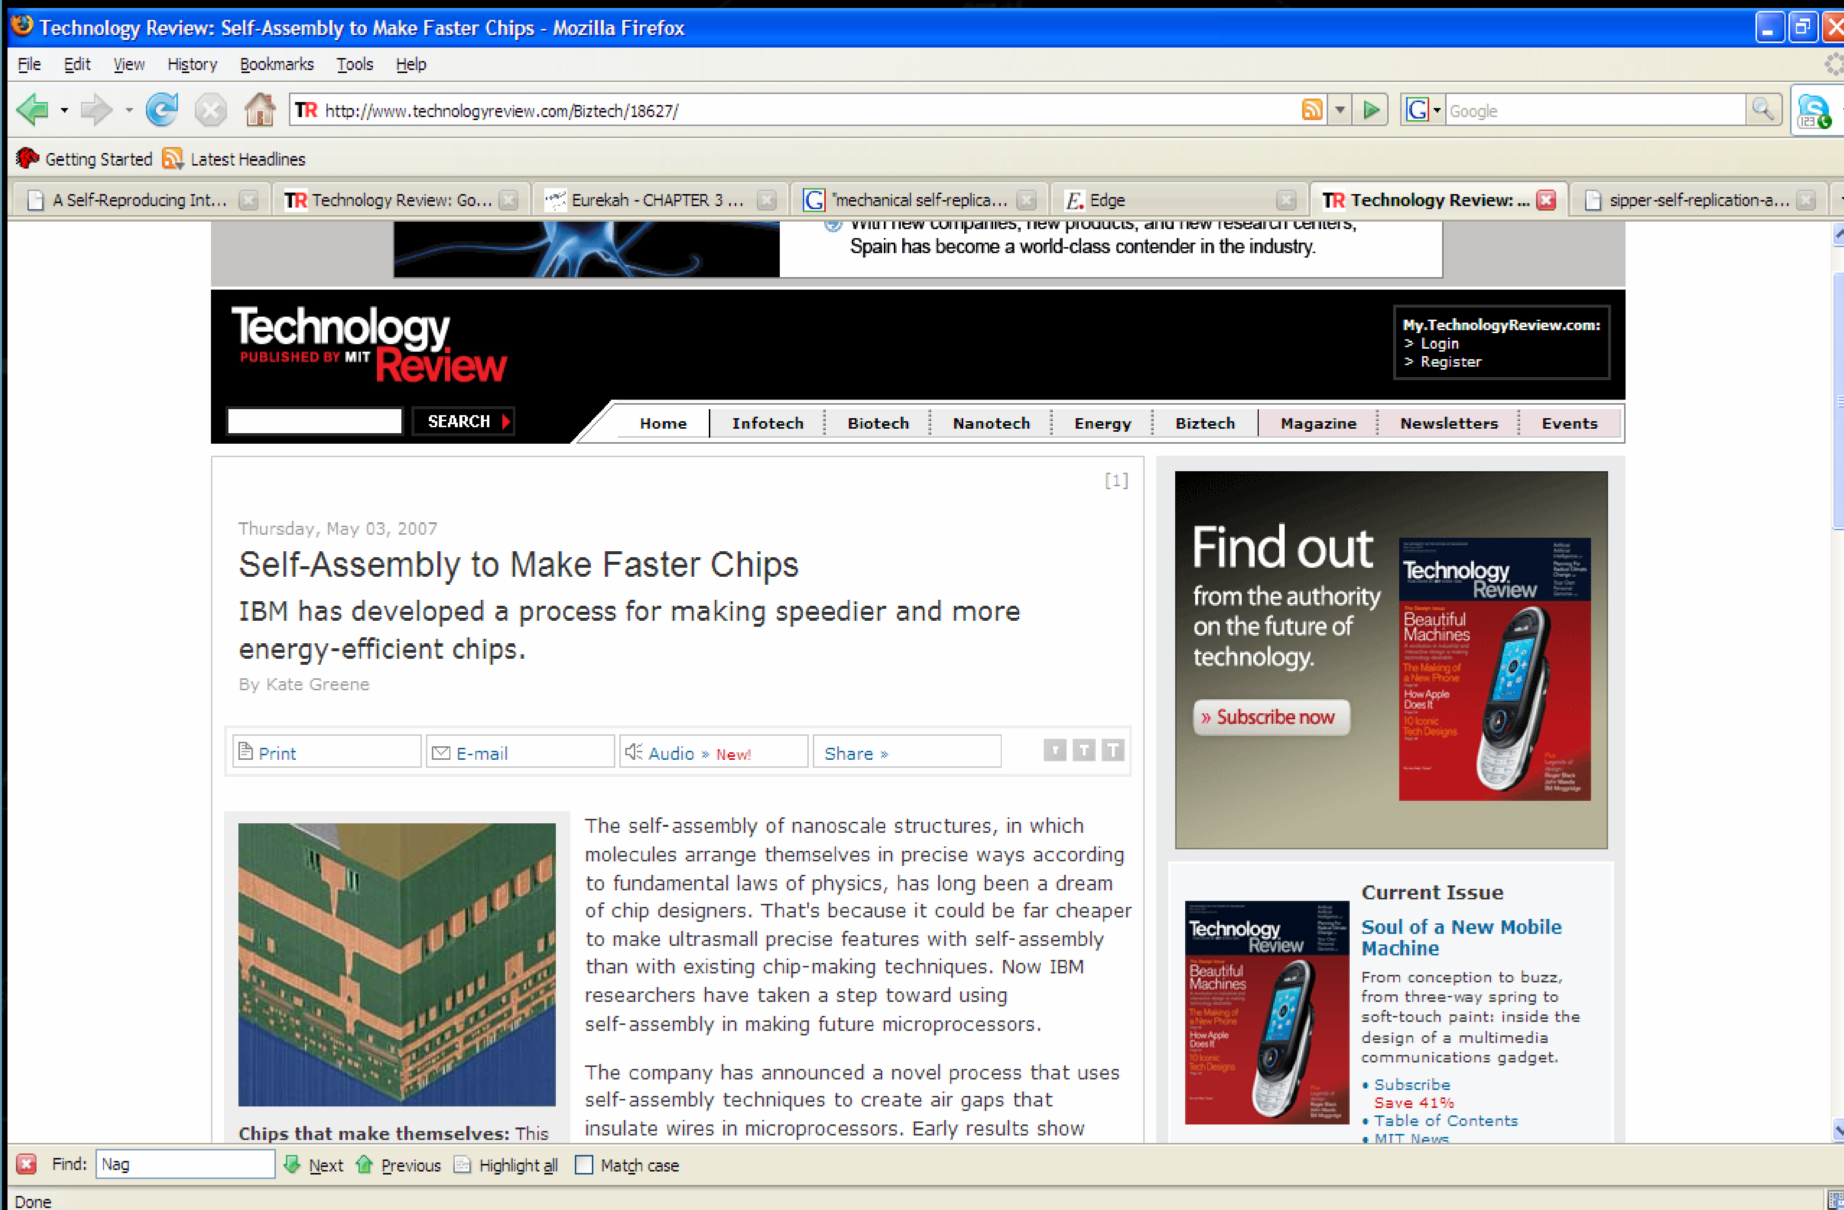
Why Self-Assembly?

Can this structure be made using self assembly?



Intel P4 (Prescott) CPU Die

Application



Features

- Complex structure emerges from local interaction of (typically) independent entities without central control
- Interactions are typically random
- SA plays important role not only in origin of living systems but also their operation
- SA can be employed as a strategy to build nano-scale structures, such as thin films or molecular wires, or to solve computational problems

Self-Assembly

There is "prior art", SA is already present in nature

- Inside cells
- Generation of biochemical complexity
- Robust self-assembly of organisms over 18 orders of magnitude in volume (self-assembly at all scales!)

Non-trivial 3D self assembly

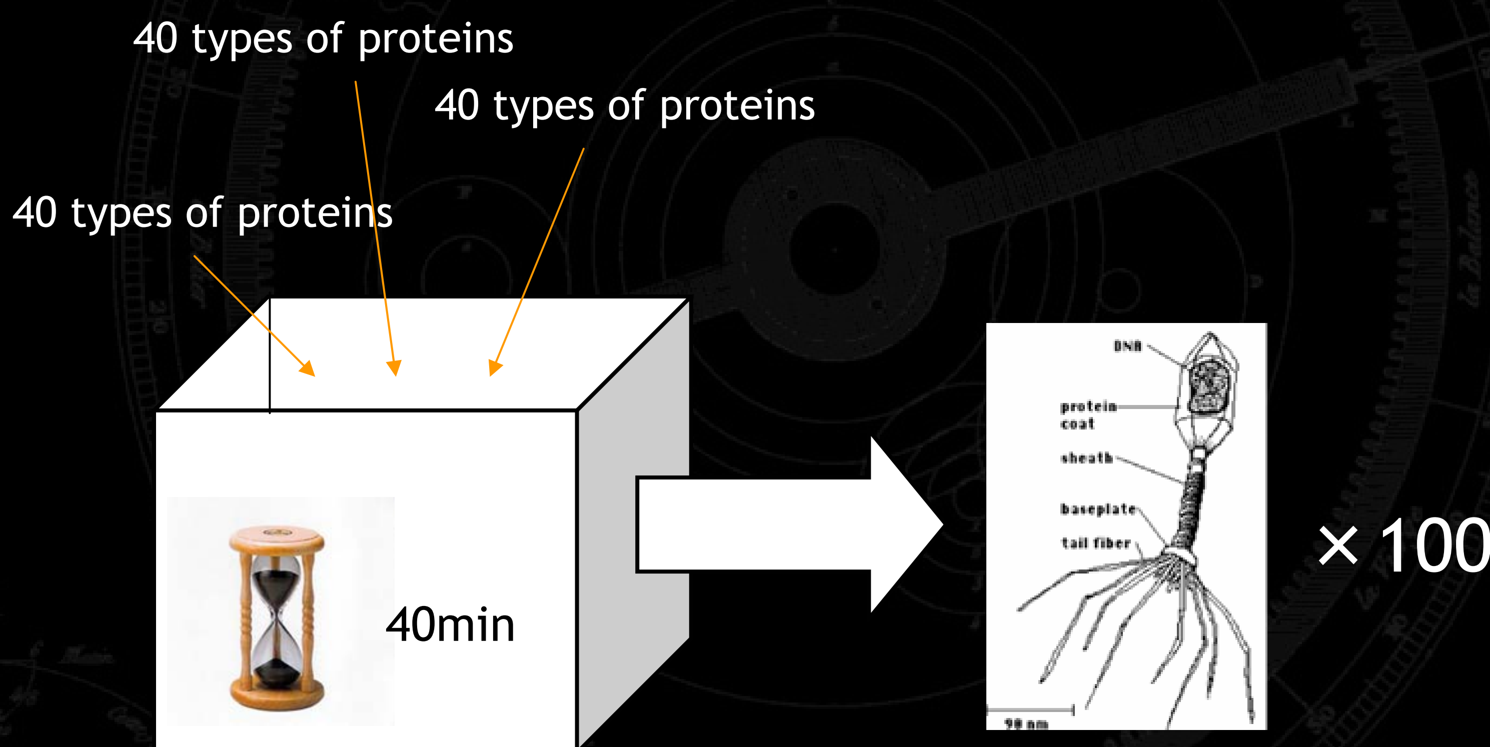
Shaken Not Stirred …



"shaking the box" of appropriate basic elements
can be sufficient for robust and efficient self-assembly

Self-Assembly

Bottom-up fabrication of complex structures:

- Arbitrary shapes can be self-assembled (2D)
- Enabled by DNA nanotechnology
- Meso-scale modeling

Tribolon: Directed Self-Assembly

Programmable Self-Assembly

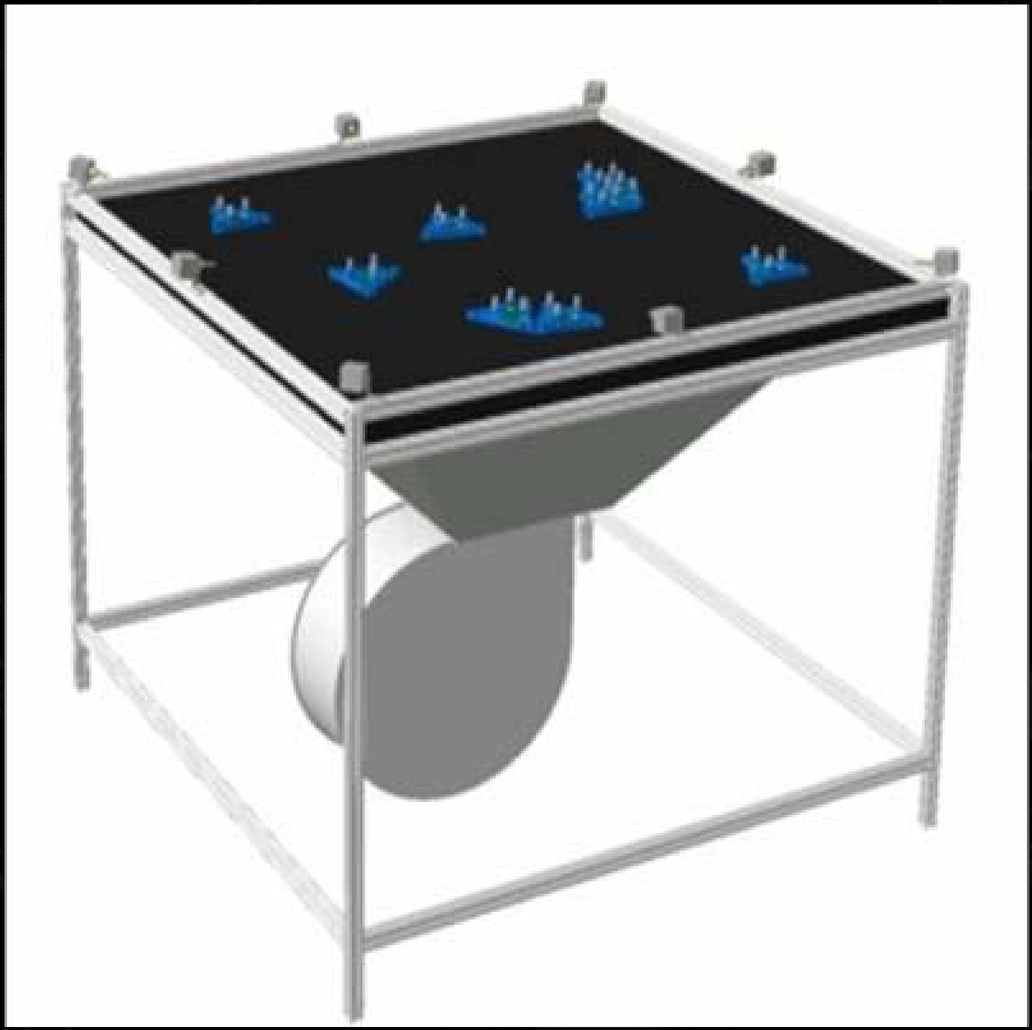
Original problem statement:

- How can we engineer complex global structures and patterns from local interactions?

New problem statement:

- How do we design local behavior that achieve <u>particular</u> global goals?
- What are the local and global <u>programming</u> paradigms?
- Can the individual components actively decide whether to bind with others?

Programmable Self-Assembly



Bishop, J., Burden, S. et al., 2005

Programmable Self-Assembly: Units

Fig. 1. Four programmable parts partially assembled into a triangle. The parts bind upon random collisions and communicate via IR, deciding whether to remain bound or to detach. A graph grammar stored on the microcontroller of each part determines the ultimate global structure that will emerge. The parts are not self-motive but instead are "mixed" on an air table by overhead oscillating fans.

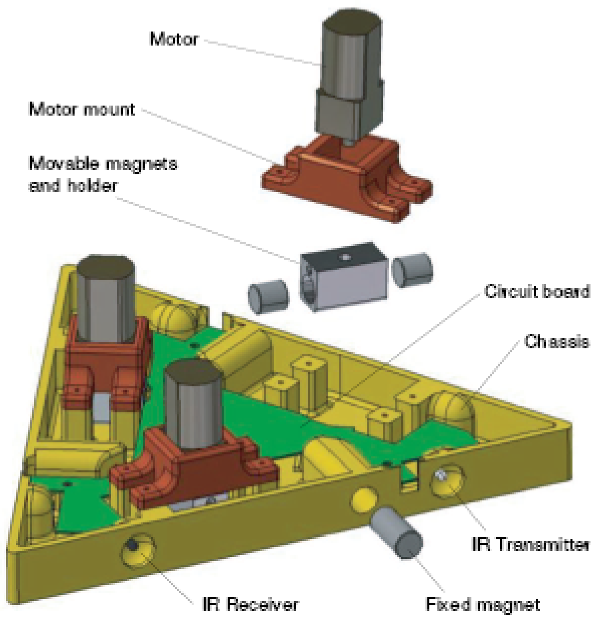


Fig. 2. The components of the programmable part include low power magnetic latches, infrared communications, and an on-board microcontroller.

Bishop, J., Burden, S. et al., 2005

Programmable Self-Assembly: Grammar

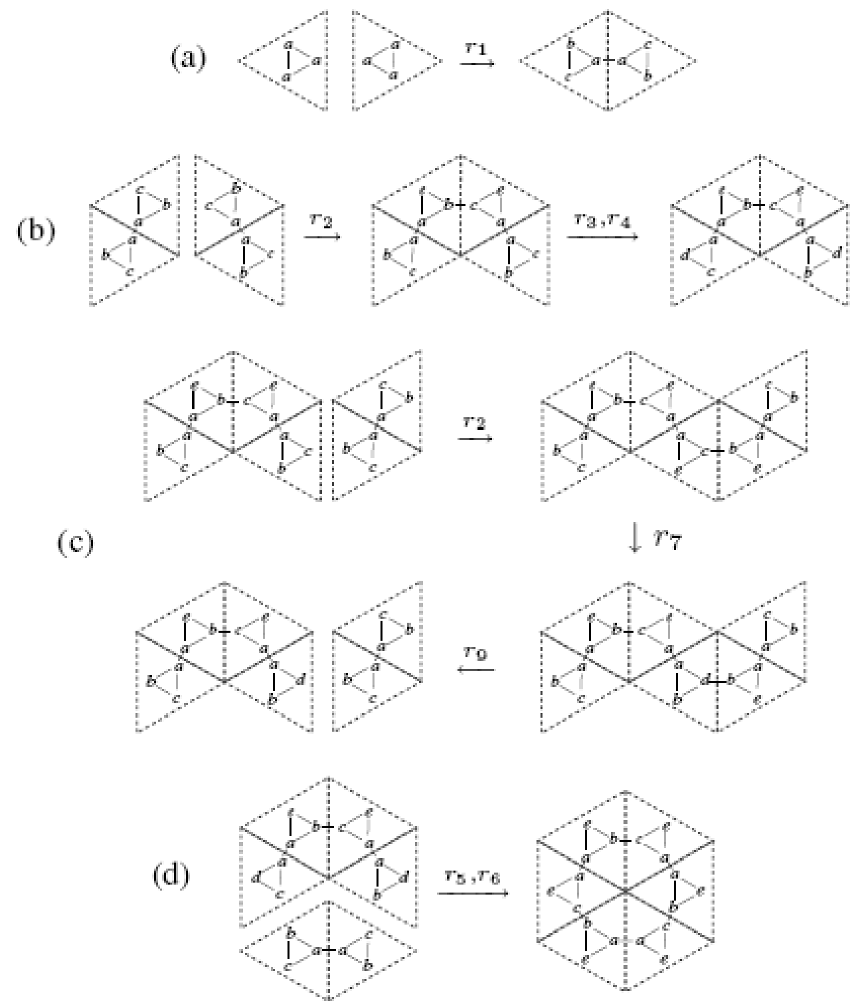

Fig. 3. The steps in the self-assembly of a hexagon using the rules described in Section V. Note that the geometry of the embedding represented here is for convenience. Graph grammars are purely topological, describing only the way the network topology of the system changes.

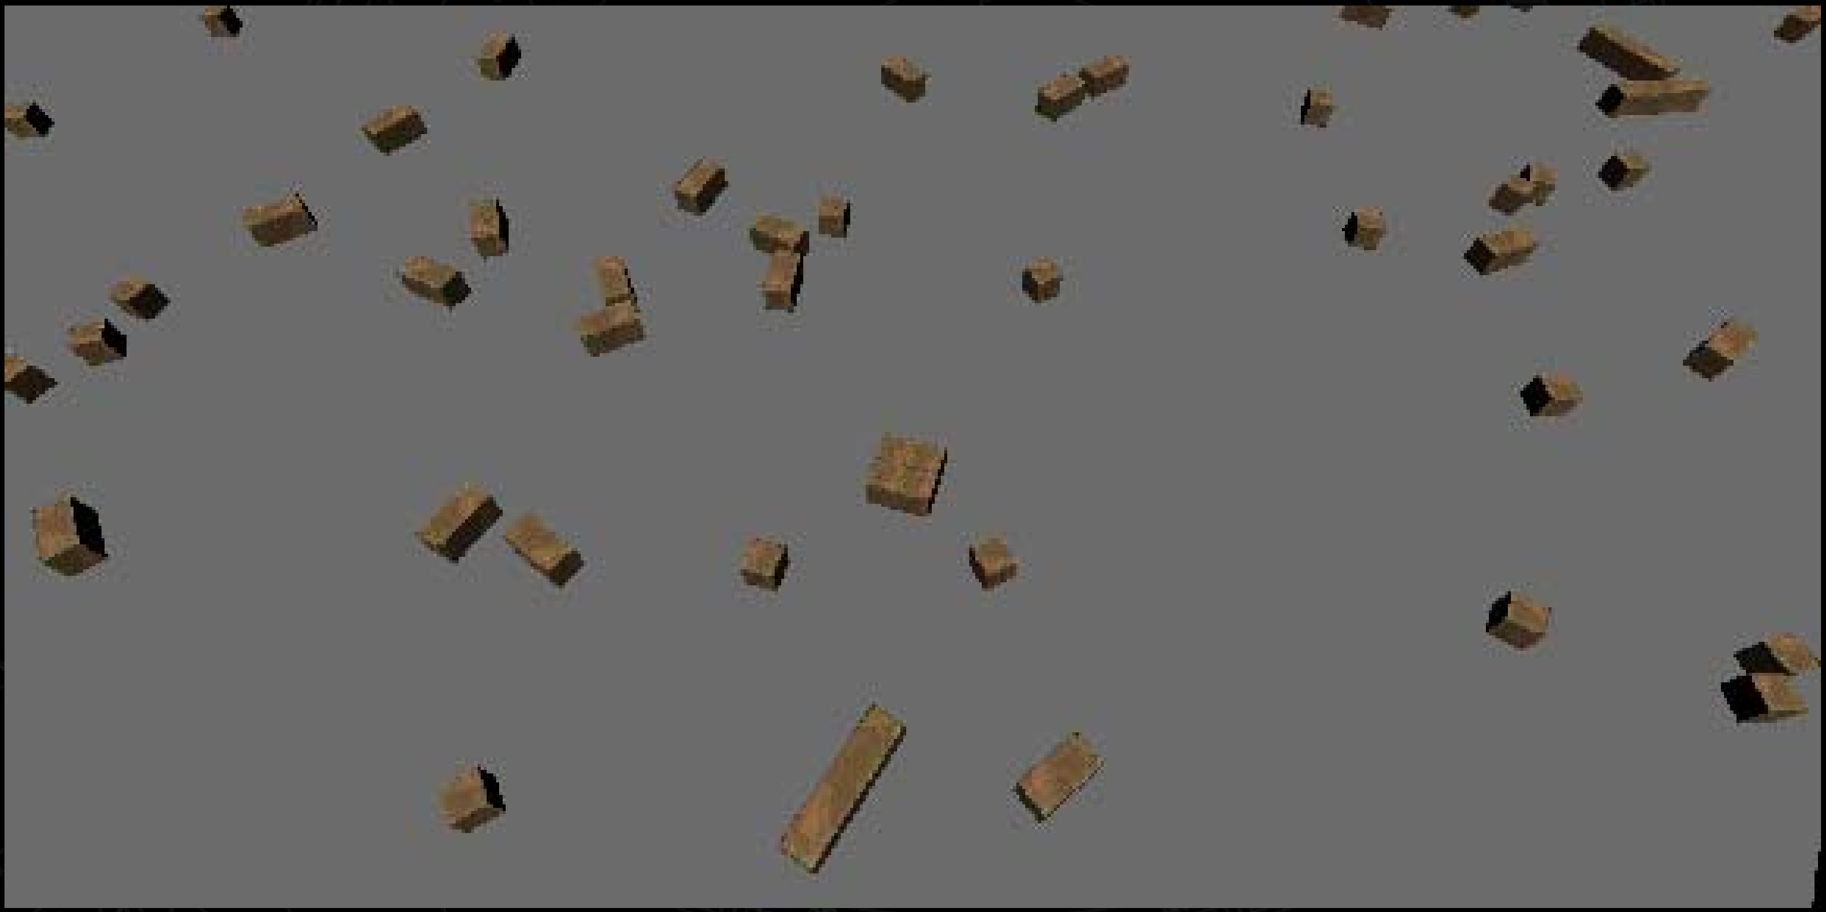
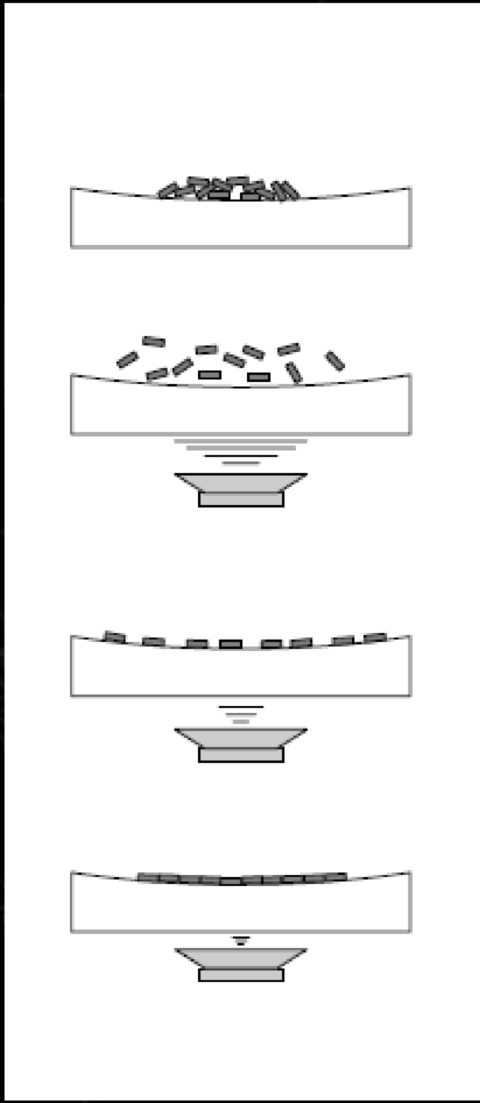
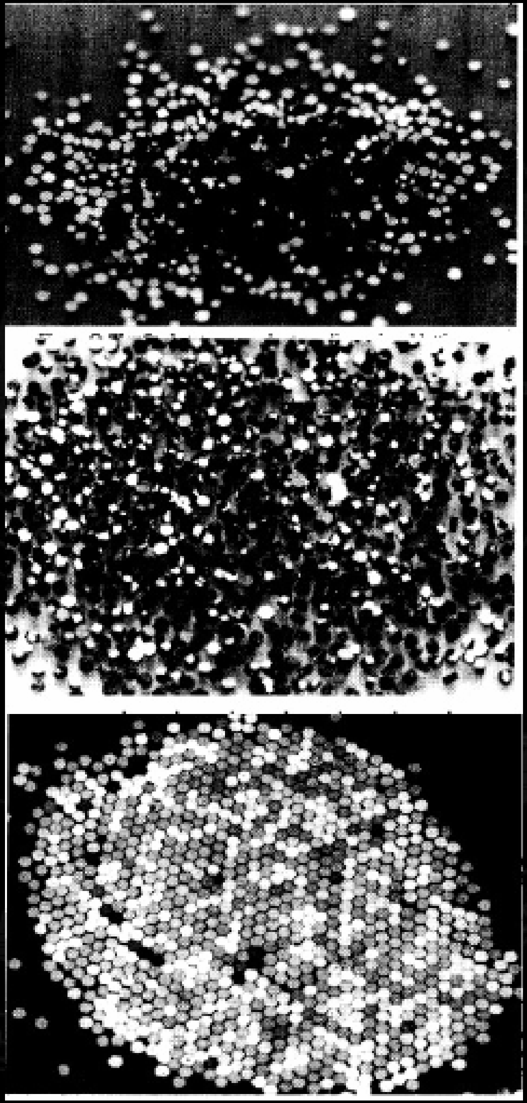
Stochastic Self-Assembly



Stochastic Self-Assembly





Cohn, Kim, and Pisano (1991)

Bottom-Up Fabrication

Biology creates very complex objects – defined from the molecular scale up to meters – that construct themselves from elementary components, and sometimes even reproduce

Scaffolded Self-Assembly of DNA

(Rothermund, 2006)

Folding DNA to Create Nanoscale Shapes and Patterns

(Rothermund, 2006)

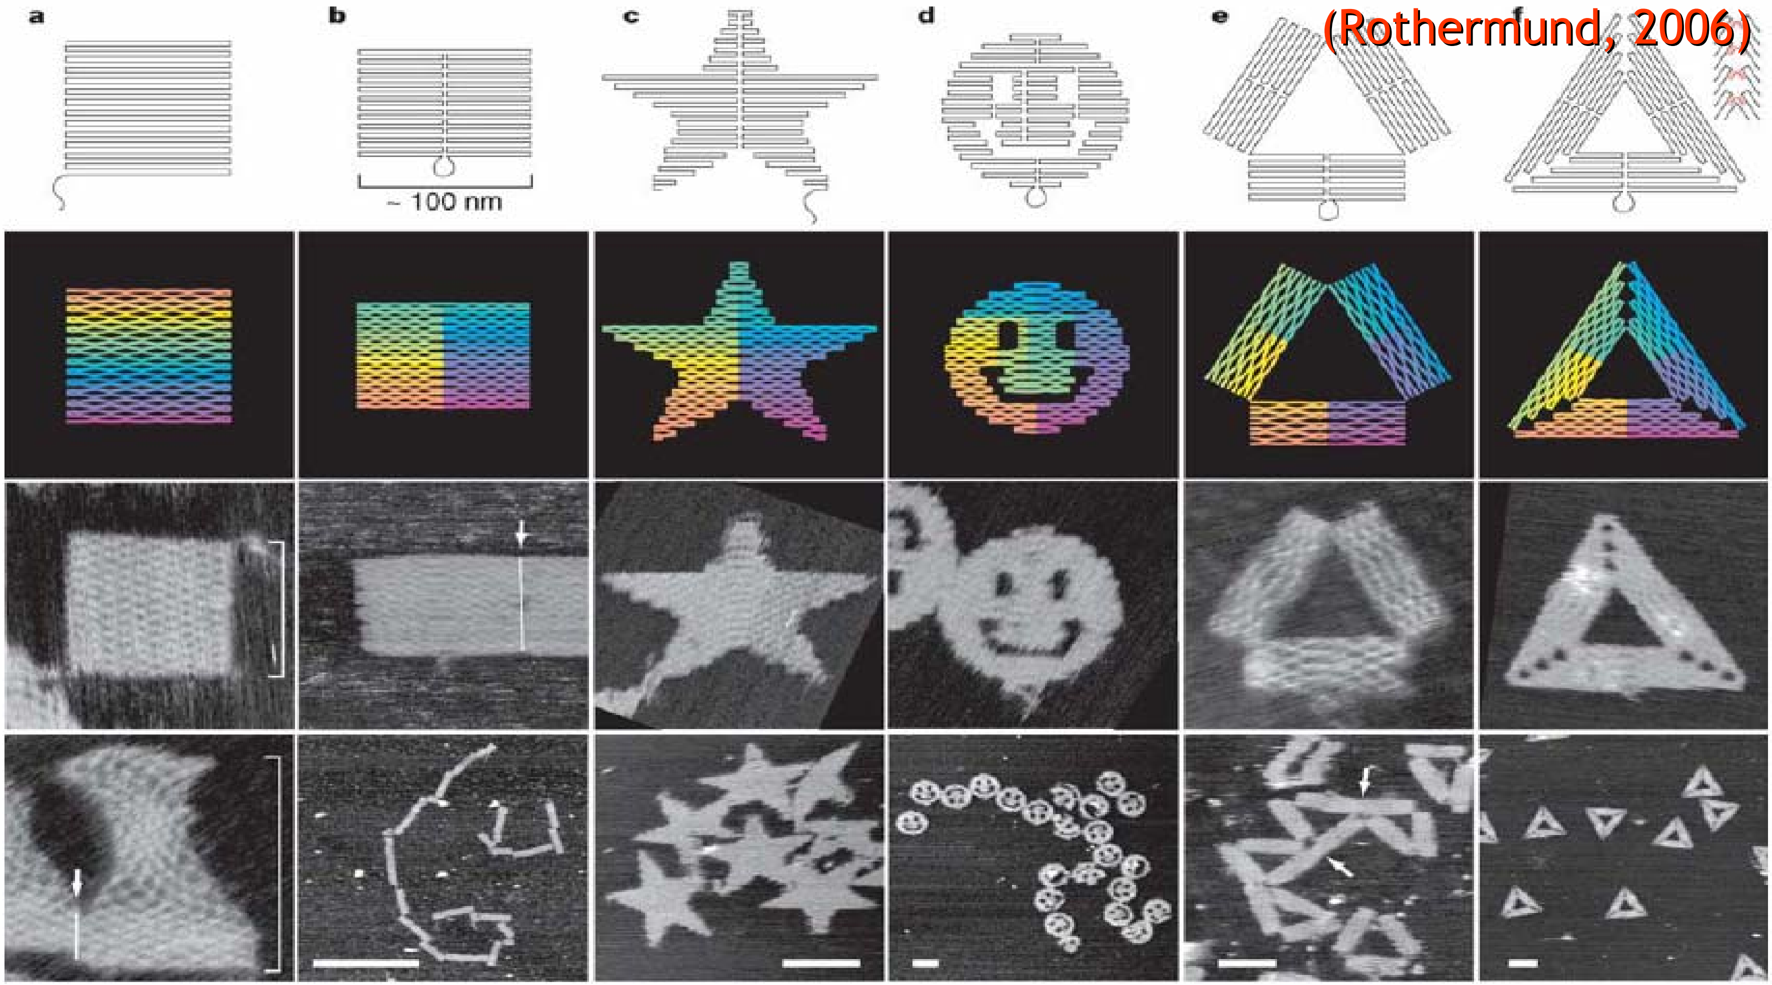


Figure 2 | DNA origami shapes. Top row, folding paths. **a**, square; **b**, rectangle; **c**, star; **d**, disk with three holes; **e**, triangle with rectangular domains; **f**, sharp triangle with trapezoidal domains and bridges between them (red lines in inset). Dangling curves and loops represent unfolded sequence. Second row from top, diagrams showing the bend of helices at crossovers (where helices touch) and away from crossovers (where helices bend apart). Colour indicates the base-pair index along the folding path; red is the 1st base, purple the 7,000th. Bottom two rows, AFM images. White lines and arrows indicate blunt-end stacking. White brackets in **a** mark the height of an unstretched square and that of a square stretched vertically (by a factor >1.5) into an hourglass. White features in **f** are hairpins; the triangle is labelled as in Fig. 3k but lies face down. All images and panels without scale bars are the same size, 165 nm × 165 nm. Scale bars for lower AFM images: **b**, 1 μm; **c**–**f**, 100 nm.

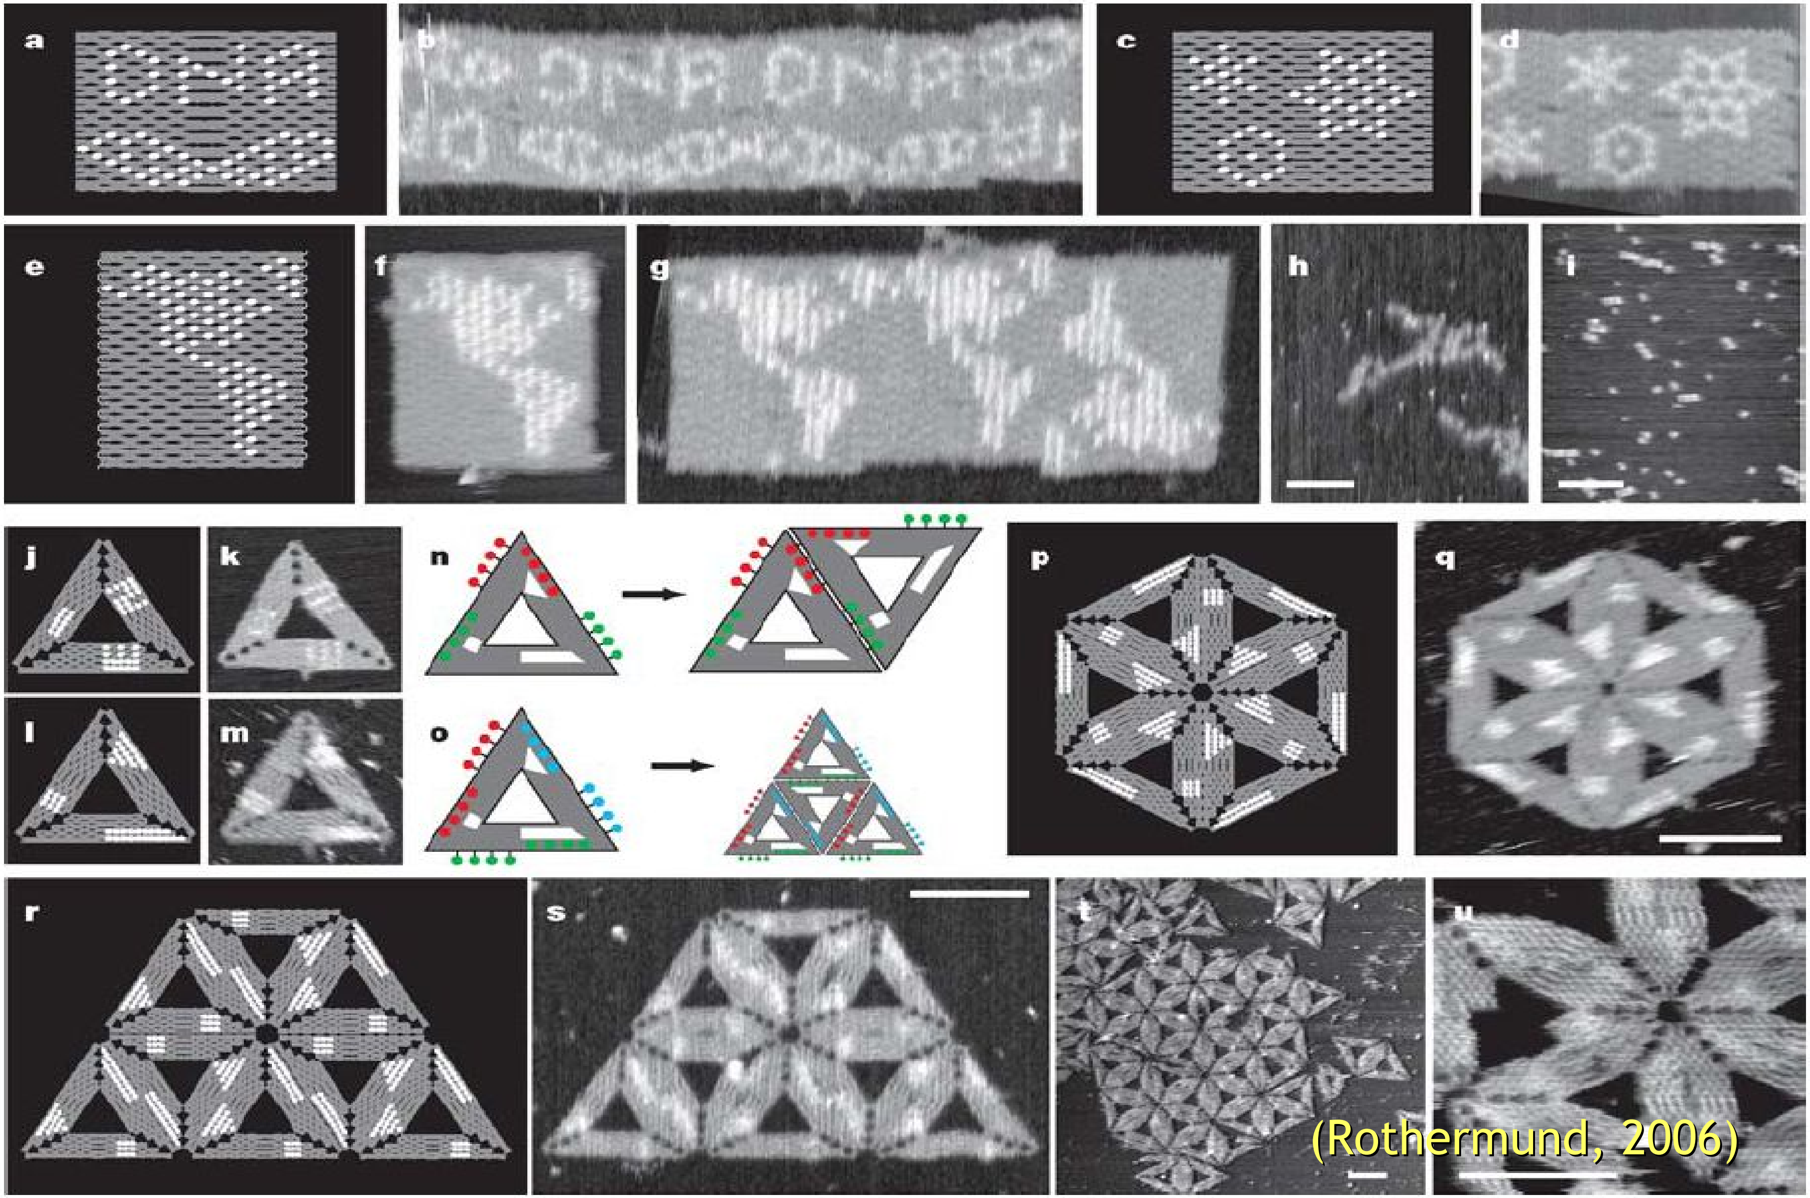
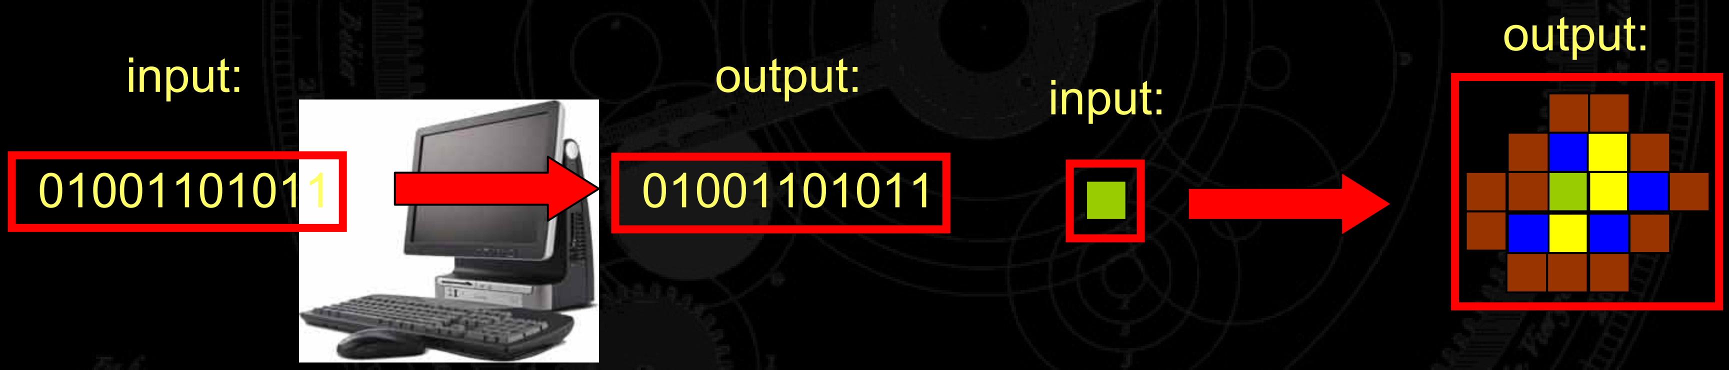
Folding DNA to Create Nanoscale Shapes and Patterns



One Particular Motivation

Compute "along the way"

- The self-assembly of a crystal can resemble a program that leaves the traces of its operations embedded in it



- The assembly of a 2D crystal can simulate a universal Turing machine!

Motivation: Self-Assembly of DNA

	DNA	Current computer
Information density (bits/nm^3)	~1	~10^{-11}
Parallelism (operations/sec)	~10^{18}	~10^{12}
Energy expediture (J/operation)	~10^{-19}	~10^{-9}

Algorithmic Self-Assembly

First A Few Words on Tiles

- A tiling is an arrangement of tiles (shapes) that covers the plane
- Tiles fit together according to matching rules: their edges must have complementary shapes and must agree on additional markings such as colors
- Tiling problem: given a finite set of tiles, does there exist a valid tiling of the plane (proven unsolvable)

The Tile Assembly Model

Infinite lattice:

- Z x Z

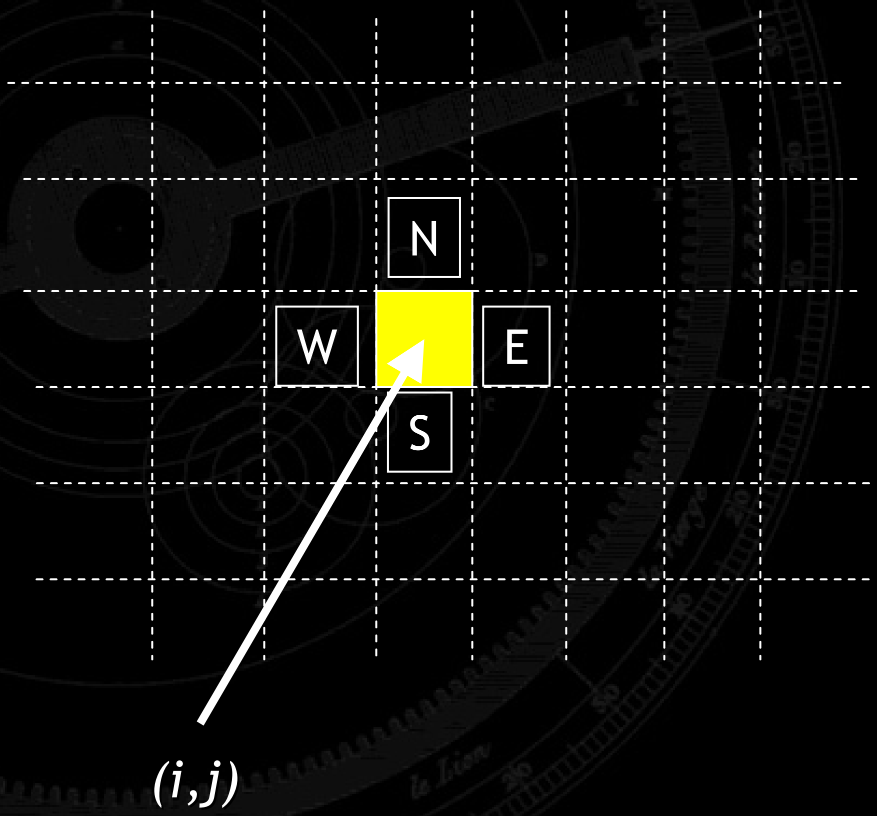
Every position in the grid has a relative position associated:

$N(i,j)=(i,j+1)$

$S(i,j)=(i,j-1)$

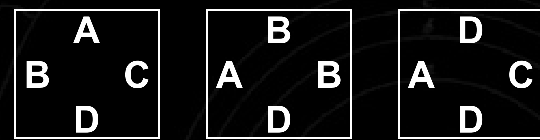
$E(i,j)=(i+1,j)$

$W(i,j)=(i-1,j)$



Bond Types and Tile Types

Our fundamental unit is a square tile with <u>labeled edges</u>, or bond types



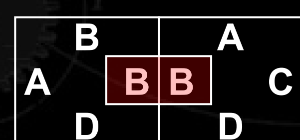
We consider a set of bond types Σ (e.g., Σ={A,B,C,D,*null*})

A reflection or rotation gives a different tile

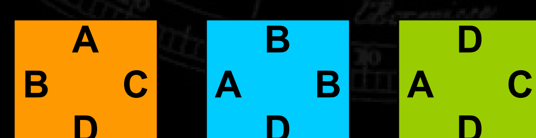
So a tile type is a quadruple: $\tilde{t} = (\sigma_N, \sigma_S, \sigma_E, \sigma_W) \in \Sigma^4$

and we have <u>unlimited</u> supply of them

Tiles types with identical edges can pair with each other



We will represent tile types with different colors. All tile types for the set *T*

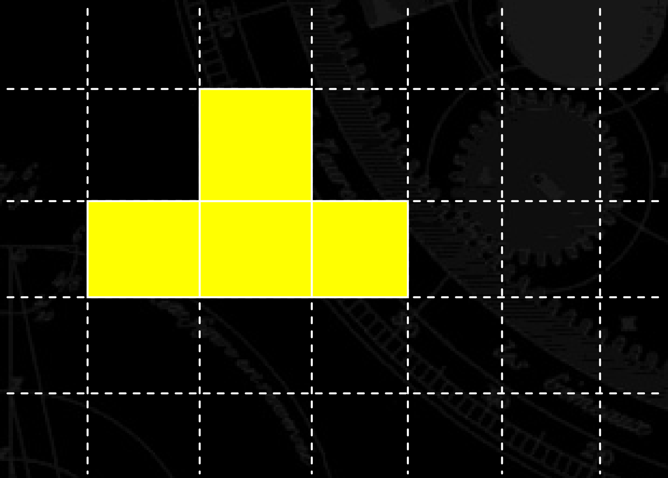


Tiles

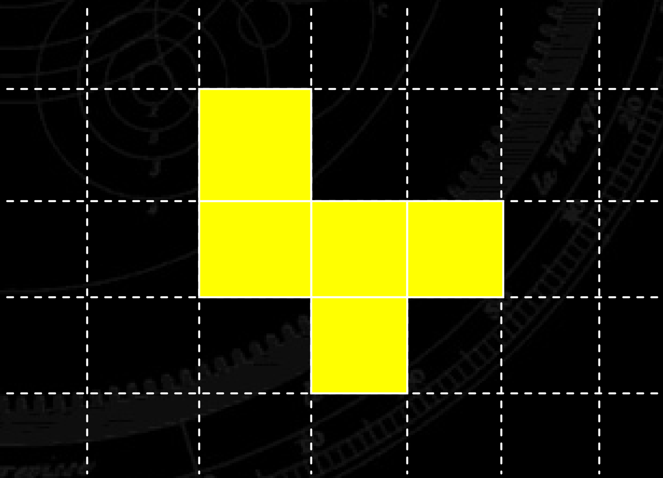
A *tile* is a pair $(\tilde{t},(i,j)) \in T \times Z^2$

i.e., it corresponds to a tile with certain tile type located in a certain position in our grid

A configuration is a set of tiles, such that there is exactly one tile in every location



Configuration 1



Configuration 2

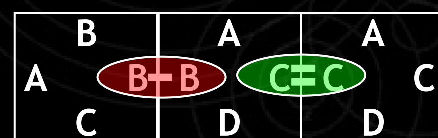
Interaction Between Tiles

A strength function $g : \Sigma \times \Sigma \rightarrow Z$ defines the interactions between two tiles.

We say a tile t_1 interacts with its neighbor t_2 with strength

$$\Gamma(t_1, t_2) = g(\sigma, \sigma')$$

g	A	B	C	D	null
A	1	0	0	0	0
B	0	1	0	0	0
C	0	0	2	0	0
D	0	0	0	1	0
null	0	0	0	0	0



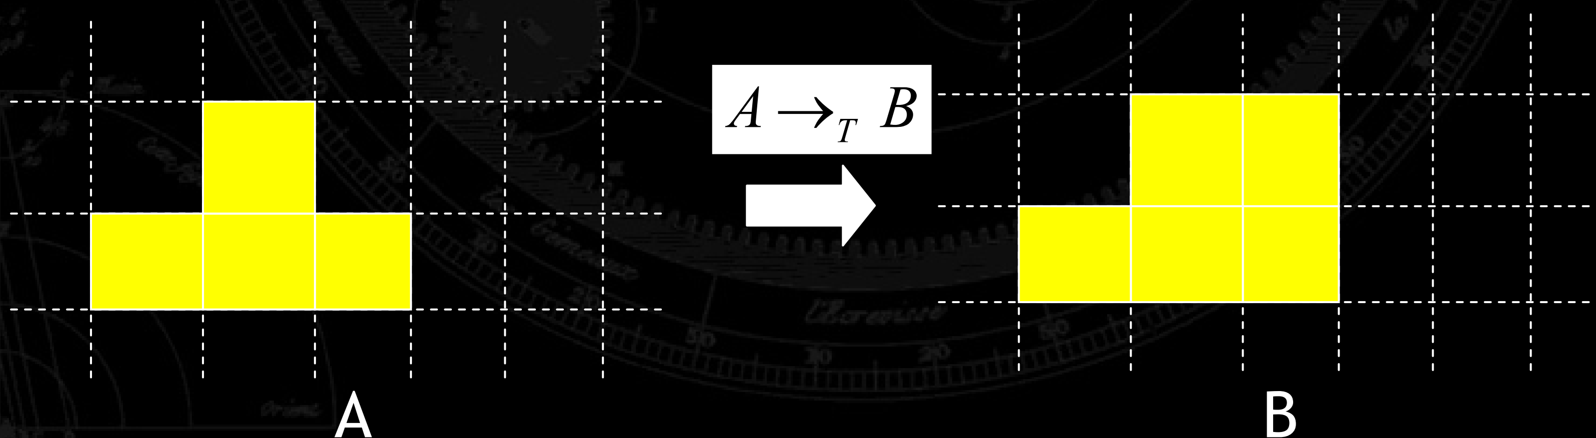
Usually, only diagonal strength functions are considered, and the range of g is {0,1,2}

The Tile Assembly Model (TAM)

A <u>tile system</u> is a quadruple (T, t_s, g, τ) i.e., it consist of

- a set of tile types
- a seed tile
- a strength function
- a binding threshold or “temperature”

Self-assembly is defined as a relation between configurations:

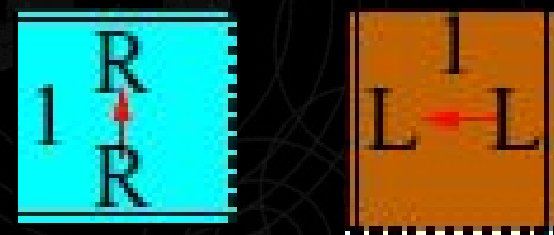


Examples of Tile Systems

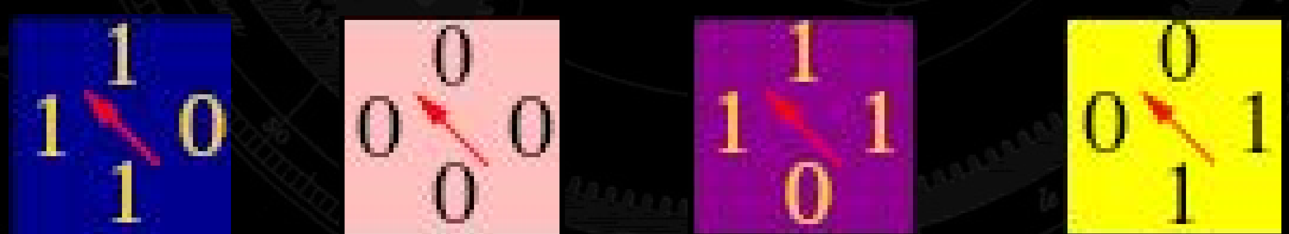
Sierpinski tile set

- 7 types of tiles: 1 seed, 2 boundary (input) tiles, 4 rule tiles

Seed

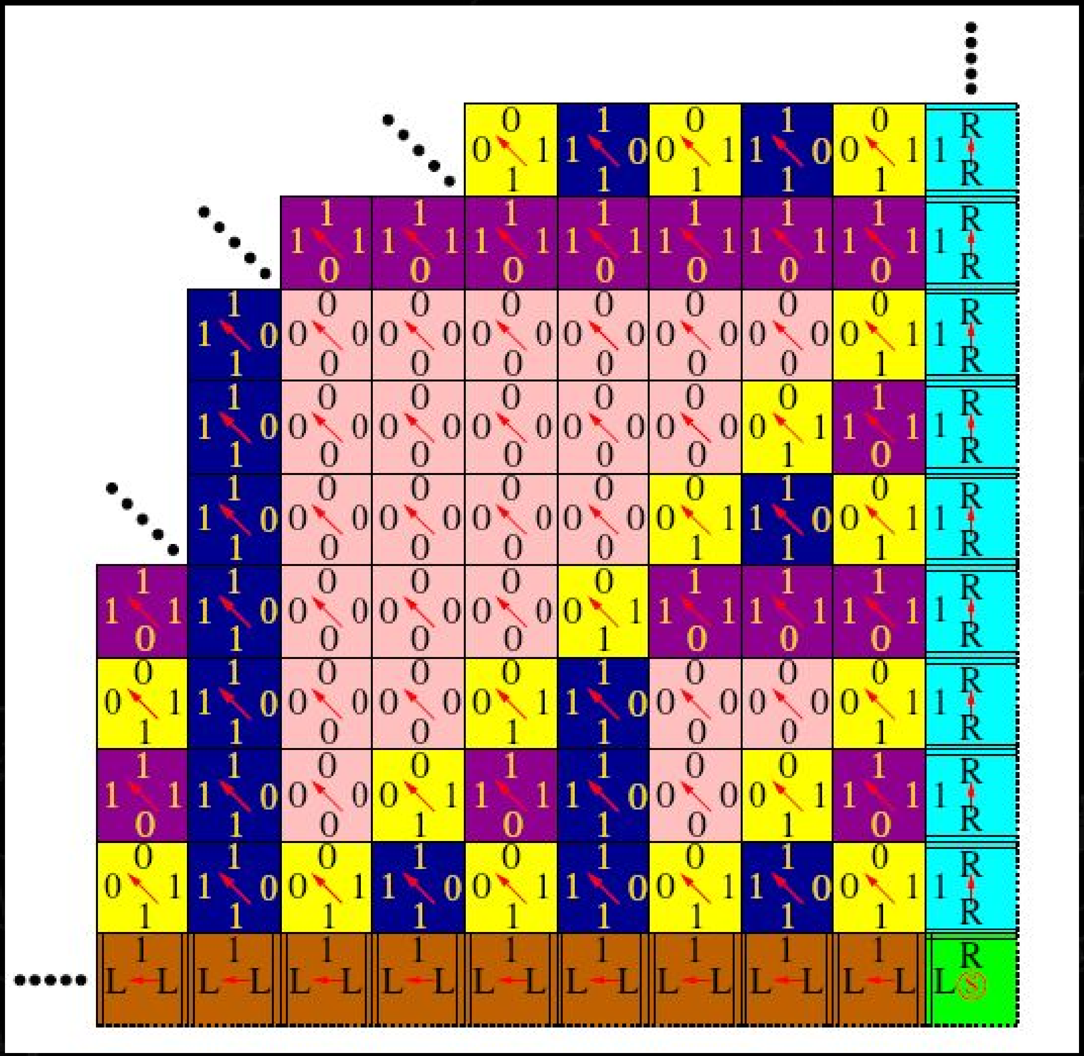


Boundary tiles

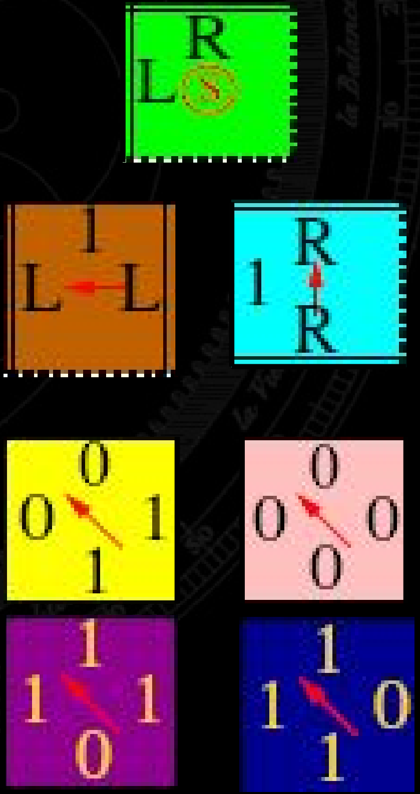


“Rule” tiles

Sierpinski Tile Set

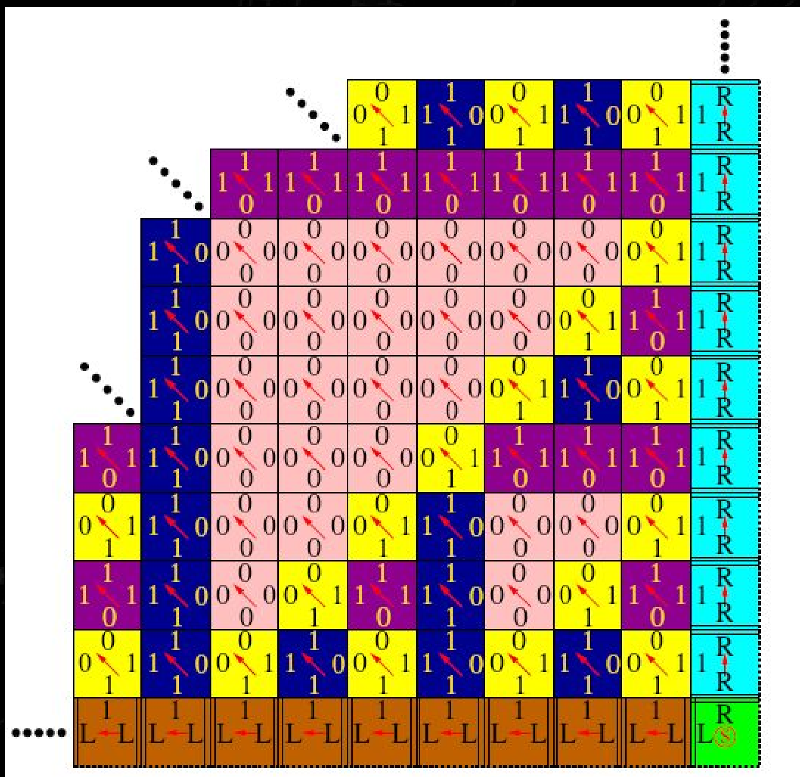


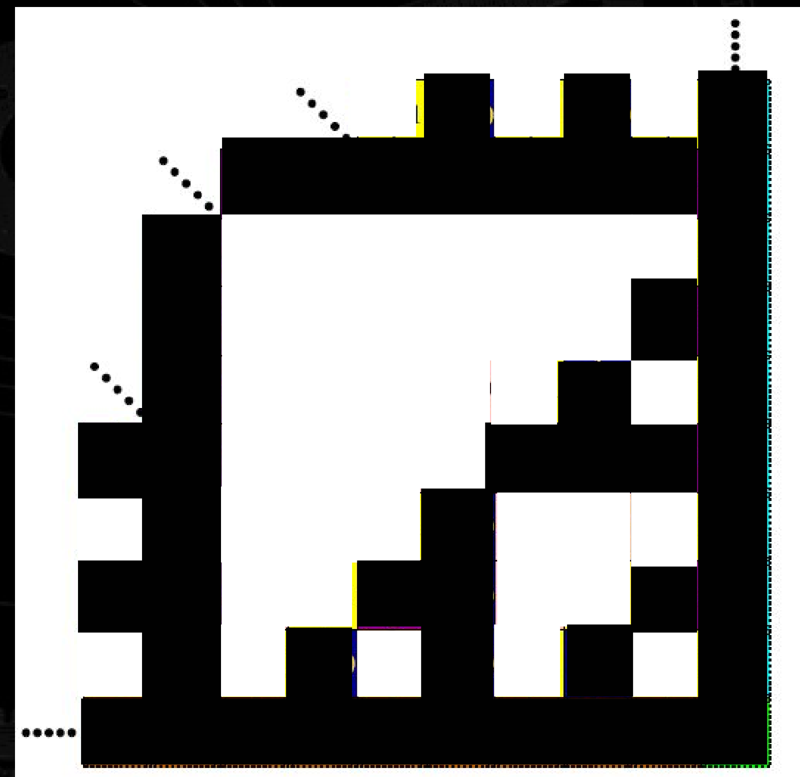
Tiles



See Winfree, Rothermund et al.

Sierpinski Tile Set

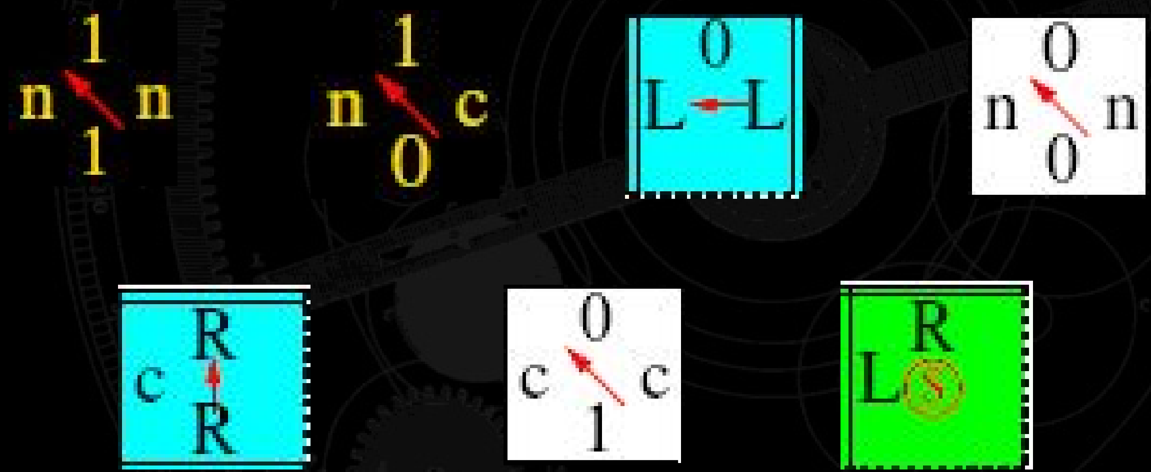




See Winfree, Rothermund et al.

Binary Counter

Tile types:



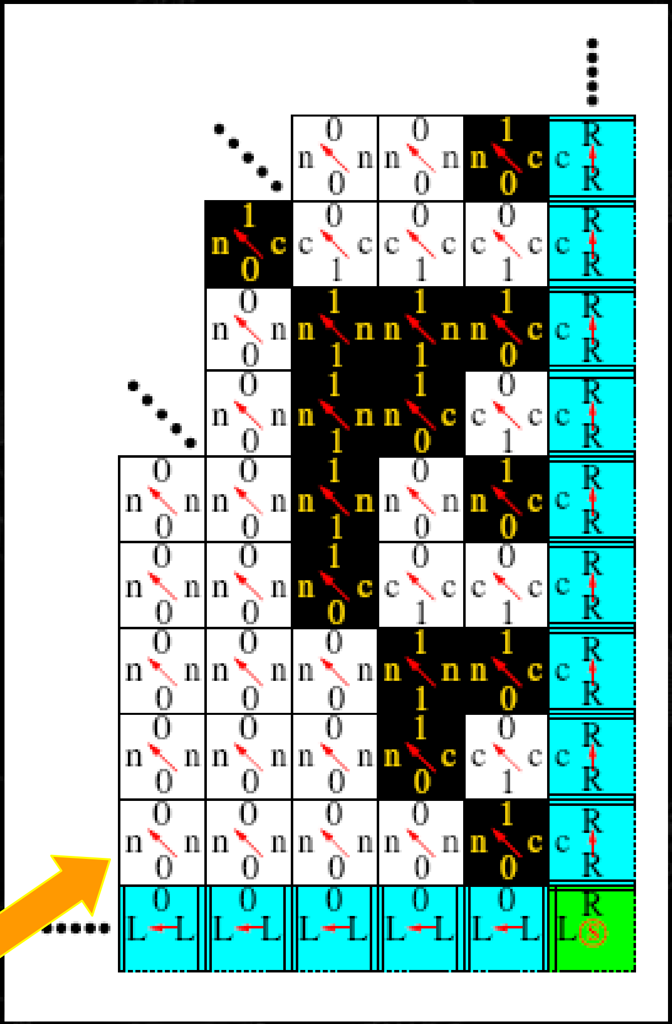
See Winfree, Rothermund et al.

Binary Counter

- Begin with seed
- Continue with boundary tiles
- Then “rule” tiles
- Count upwards (binary)

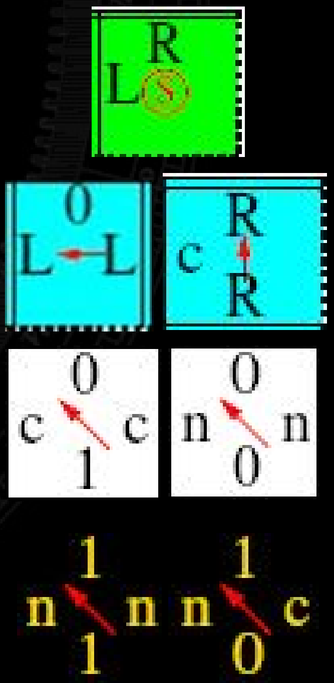
= 1

= 0



00001

Tiles

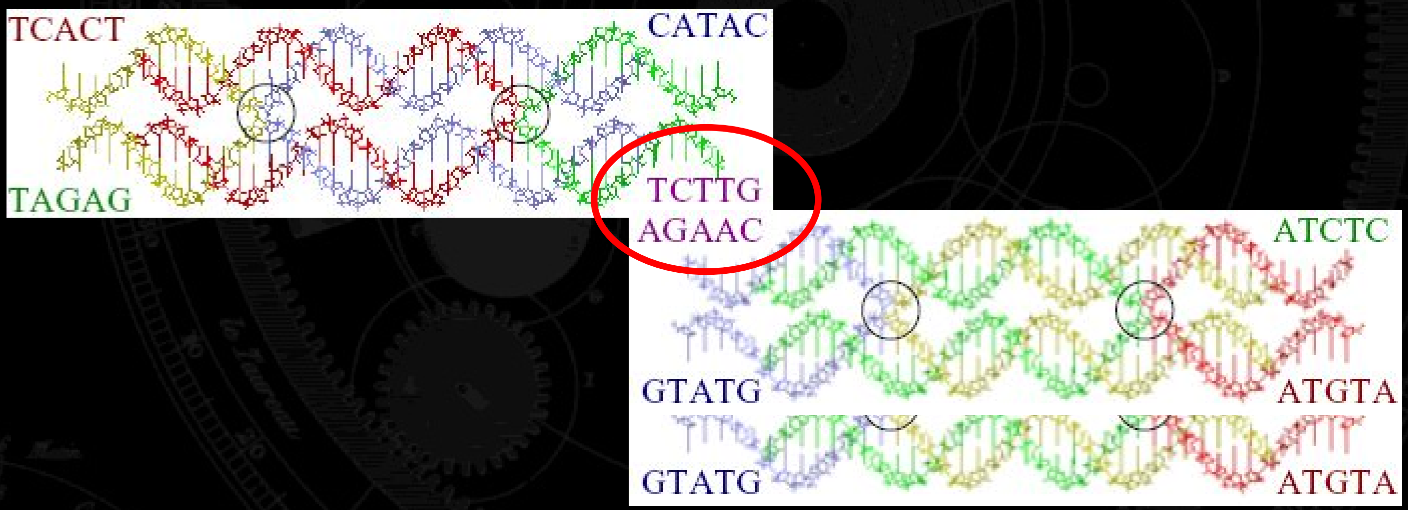


See Winfree, Rothermund et al.

From Theory to Practice (Biology)

Tiles are "do-able" in practice

DNA Nano-technology



Winfree, E. et al. (1998). Design and self-assembly of two dimensional DNA crystals

Protocell Assembly - Ongoing

- Question is not whether simple life-forms can be assembled but under which conditions it can occur
- Bottom-up routes to artificial (proto)cells
- Ultimate goal: living artificial cells made from non-living material

http://protocells.lanl.gov/

http://www.protocell.org/

http://bruckner.biomip.rub.de/bmcmyp/Data/PACE/WWW/PACE/index.html

PACE Project

Artificial cells = living matter

Computational aspects of living matter/artificial cells:

- <u>Design</u> of artificial cells (relies on self-assembly)
- <u>Programming</u> artificial cells (low-level assembly language still needs to be discovered)
- Computational potential of artificial cells (programmability of functionality; programmability of pattern)

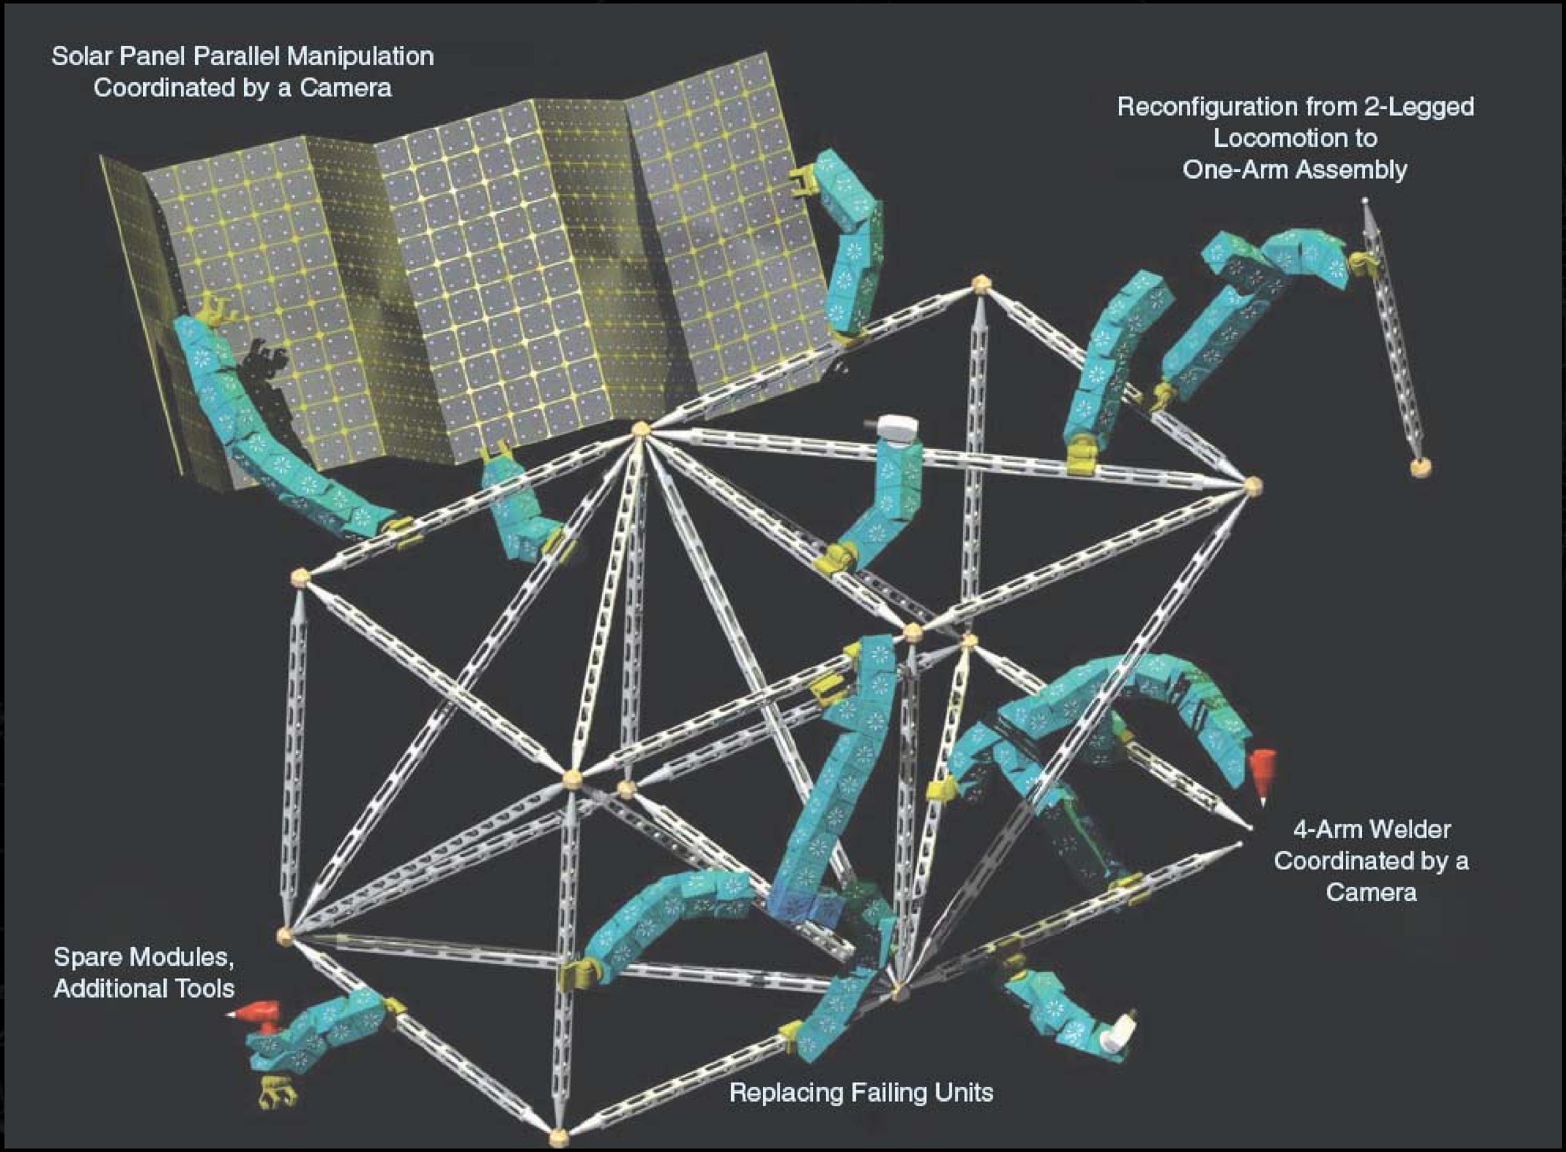
Synthetic/Systems Biology

Beginning of Norman Packard’s talk

Modular Self-Reconfigurable Robots

- Modules are connected
- Modules can change form (variable morphology)

Application Scenario



(Zykov et al., 2007)

The Robosphere

***Figure 1:** Artists impression of self-replicating lunar factory.*

????

http://robosphere.arc.nasa.gov/

Motivation and Inspiration

- Versatility and adaptivity (new morphologies better suited for the task)
- Robustness (parts are interchangeable → self-repair)
- Low cost (many copies of a few types of modules)
